

Model Evaluation – Final Summary

The model shows **good performance** in predicting mobile prices. The **R^2 score of 0.8112** indicates that the model explains approximately **81.12% of the variation in mobile prices**. The **MAE of 252.51** means that the model's predictions differ from the actual prices by approximately **252.51 units on average**, while the **MSE is 92,877.41**.

Overall, the model provides a **reasonably accurate prediction of mobile prices**. However, its performance could be improved by including more relevant features, handling outliers, tuning model parameters, and testing other machine-learning algorithms
